"The Welding of Titanium-Bearing 80-20 Nichrome" (Avto. Delo, 1952, 23, July, p. 7)

Type KhN78T (19-20 per cent. Cr, 1 per cent. Fe, $\frac{1}{4}$ per cent. Ti) nichrome is usually welded by argonarc or resistance welding. It is shown that excellent are welds are produced using parent metal wire with a standard nichrome-type coating, provided care is taken to minimize chromium and titanium losses by depositing small runs at high welding speeds.

AUTHOR: Gorokhovskiy V. M., Gorkhovskaya, V. I. and Nigmatullin, R. S.

TITLE: The oscillographic polarography of some organic compounds

PERIODICAL: Referativnyy zhurnal, Khimiya, no. 5, 1963, 83, abstract 5B597, Teoriya i praktika polyarogr. analiza, "Shtiintsa", 1962, 63-67)

TEXT: With the aid of the oscillographic polarograph with triangular enolution, oscillographic polarograms (OP) of photographic reagents were obtained with dropping Hg electrode: hydroquinone (I), quinone (II), pyrocatechol (III), resorcinol (IV), hydroxyphenylglycine (V), o- (VI), n- (VII), and m-aminophenols (VIII), methyl VII (IX), 2-aminobenzothiazols (X) and its derivatives, 5,7 diamino-2,3,4,6-tetrazoindolycine (XII) and 5,7 dimethyl-2,3,4-triazoindolycine (XIII). A study was made of the dependence of the height of the peak i_{π} on the rate of scan of potential V in the 30-350 volt/sec interval for I and X, and also the dependence of potential of the peak E_{π} on pH and the magnitude of the potential difference of anode and cathode peaks for I, II, III, VII, XI. I, III, V, VI, VII and IX are reduced reversibly and III and VIII irreversibly. The OP of compound X contains two anode-cathode peaks ($E_{\pi} = 1.1 - 1.2$ v vs SCE) and OP of alkaline solutions

Card 1/2

L 12363-63

S/031/63/000/005/011/075 0

The oscillographic polarography

of X and its derivatives contain new peak ($E_{1/2} = 0.78$ v). It is noted that $i_{1/2}$ of the latter does not depend on v. There are no sharp changes in the capacity current on the OP of compound XI and its derivatives with changes of the potential, but on the OP of compounds XII and XIII such phenomenon is observed. The article discusses the connection between the demonstrated capabilities and the appearance of the reversible anode-cathode peaks. A.E.

Title : The Investigation of Complexes of Copper with Aromatic Acids and Phenols by the Method of Oscillographic Polarography

Orig Pub: Uch. Zap. Kazanskogo un-ta, 1956, Vol 116, No 1, 162-166

Abstract: A dropping-Hg electrode was used to record the oscillograms (O) of the current-voltage curves for Cu^{2+} solutions containing sodium salicylate (I), thiosalicylic acid (II), pyrocatechol (III), sodium p-aminosalicylate (IV), guaiacyl potassium sulfonate (V), sodium acetylsalicylate (VI), and phthalic acid (VII) on a background of NaNO_3 as well as of a Cu^{2+} solution containing no organic substance and of a solution of Cu^+ in the presence of Na_2SO_3 on a background of Na_2SO_4 . The O of Cu^{2+} ions on a background of NaNO_3 is asymmetrical, showing two peaks in the cathodic region and one peak in the anodic region; it is assumed that the irreversible reaction $\text{Cu}^{2+} + e \rightarrow \text{Cu}^+$ (unsym-

Card : 1/2

Abs Jour: R Zh--Kh, No 3, 1957, 7692

metrical section of 0) is followed by the reversible step $\text{Cu}^{+} + e \rightarrow \text{Cu}$ which competes with the disproportionation reaction $2\text{Cu}^{+} = \text{Cu}^{2+} + \text{Cu}$. The 0 of the Cu^{+} solution is symmetrical; this is confirmed by the reversible character of the reaction $\text{Cu}^{+} + e \rightarrow \text{Cu}$. When e is shifted towards negative values, the part played by the reduction of Cu^{+} increases. The 0 of solutions of I-VII have the same shape and differ only in the magnitude and form of the peaks; it is assumed that in the solutions of I-VII only the complex $\text{Cu}(2+)$ exists and is reduced reversibly. The appearance of 0 depends on the structure of the complexes formed by I-VII and on the pH of the solution.

"The chemical nature and properties of "necrosin" (Macrocytase) and the haemolysin of inflammatory exudates (Russian text) ARKH. PATOL. 1953, 6 (13-26) Graphs 3 Tables 5 Illus. 1

Menkin's theory of inflammation is submitted to critical analysis, and a personal method of obtaining pure necrosin in dissolved form is described. It appears to be a pseudoglobulin and is a proteolytic enzyme of the trypsin type, with an optimum at pH 7.7-8.2. Particization of proteins initially takes place without splitting of peptide bonds; the latter only occurs after prolonged incubation with the enzyme. Reagents which inhibit trypsin and form compounds with metal cations, prevent further proteolysis by macrocytase. The proteolytic action of macrocytase caused cutaneous necrosis in mice. The biological effect of the preparation is influenced by the nervous system. The haemolysin of inflammatory exudates - first described by Tarasevic - is a higher unsaturated fatty acid. It occurs in combination with macrocytase and can be separated from the latter with the aid of ether or butanol. Brandt-Berlin

Enzymic properties of necrosin (macropptase) of inflammatory exudates. V. Z. Gorkin and M. N. Kondrashova (Inst. Biol. and Med. Chem., Acad. Med. Sci. U.S.S.R., Moscow). *Biokhimiya* 18, 288-95(1953).--Necrosin (I) was obtained from exudates of experimentally produced inflammatory processes in the pleural cavity and subdermal tissues of the dog by injection of turpentine, as well as from purulent exudates obtained from hospitalized cases. After preliminary partial removal of nucleoproteins, the exudates were fractionated by $(NH_4)_2SO_4$. The protein fractions thus obtained were freed from sulfate by dialysis, dried, and stored in the cold. They were suspended in 0.9% NaCl and injected intradermally into mice. In the presence of I dermonecrosis appeared at the point of injection. Studies of the proteolytic properties of the purified and unpurified substances were carried out. A soln. of the protein substrate (usually denatured β - + γ -globulins of blood serum) in 0.9% NaCl, buffer, I, and toluene were incubated at 37°. Fixation was by means of trichloroacetic or acetic acid. Amino N was detd. with the Van Slyke app., residual N by micro-Kjeldahl, and unchanged protein by the biuret color reaction. Results were recorded after 24 and 48 hrs. The authors conclude that I of inflammatory exudates is a proteolytic enzyme of the type of trypsin, having an optimum pH 7.7-8.2. It splits a variety of proteins and possesses fibrinolytic properties. In the initial stages of I activity (as well as of crystalline trypsin) on the proteins there appears the process of peptization with a concomitant high increase in amino N, which starts after a prolonged period of incubation. Metallic cations which impede the proteolytic activity of trypsin have a similar impeding effect upon the protein-splitting power of I. No such effect is observed in the process of protein peptization by I or by crystalline trypsin. The ability of I to cause dermonecrosis is dependent upon its proteolytic properties. B. S. L.

MD ✓ Chemical nature of hemolysin from inflammation exudates. V. Z. Gorkin. *Doklady Akad. Nauk S.S.S.R.* 90, 837-40 (1953); cf. Pönder, C.A. 45, 7173f. Hemolysin from suppurative exudates (having pH 5.3-6.4) is found in the 1st protein fraction pptd. by $(\text{NH}_4)_2\text{SO}_4$; it has hemolytic and cytolytic activity. Purification of such an exudate obtained from a dog, in which inflammation was induced by injection of turpentine, was accomplished by pptn. with $(\text{NH}_4)_2\text{SO}_4$, extn. with ac. BuOH, followed by extn. with $\text{Et}_2\text{O}-\text{H}_2\text{O}$, pptn. with $\text{Pb}(\text{OAc})_2$, and treatment of the ppt. with $\text{EtOH}-\text{AcOH}$. The lytic activity resides only in the fraction of unsatd. fatty acids with iodine no. 50, and contg. 72.24% C and 10.99% H, which is close to the compn. of a C_{21} olefinic acid. G. M. Koschepoff

Electrophoretic studies of protein fractions in the serum of animals suffering from rheumatoid arthritis and from chronic osteomyelitis. (Submitted for publication 11/10/66, No. 1041, 1966, 38).
 The results of electrophoretic studies of the serum of animals suffering from rheumatoid arthritis and from chronic osteomyelitis are presented. It is shown that in the serum of animals suffering from these diseases there is a significant increase in the content of α_2 and β globulin fractions and a decrease in the α_1 fraction. This may be due to the fact that in chronic diseases such as rheumatoid arthritis and chronic osteomyelitis there exists a simultaneous inflammatory process of the surrounding soft tissues.

"Recent Advances in the Biochemistry of Inflammation, Part 2," by V. Z. Gorkin, Laboratory of Nitrogen Metabolism (scientific director, Prof A. Ye. Braunshteyn, Active Member, Academy of Medical Sciences USSR), Institute of Biological and Medical Chemistry (director, Prof V. N. Orekhovich, Active Member, Academy of Medical Sciences USSR), Academy of Medical Sciences USSR, Ekspperimental'naya Khirurgiya, No 6, Nov/Dec 56, pp 57-60

Chemical compounds which can alter the course of the inflammatory process are being studied intensively. Among these are the corticosteroids (cortisone, hydrocortisone, the desoxycorticosterones, aldosterone, etc.), and adrenocorticotrophic hormone, and the growth hormone of the anterior hypophysis.

The physiological effect of the above compounds on the inflammatory process is discussed on the basis of data available in the literature.

TITLE: Effect of ultrasonic waves on monoaminoxidase bound to submicroscopic mitochondrion structures

SOURCE: Biofizika, v. 9, no. 4, 1964, 503-506

[illegible]

microscope

ABSTRACT: Mitochondrion suspensions prepared from white rat livers were exposed to ultrasonic waves to demonstrate that sonication could rupture structures containing membrane proteins. The released proteins were detected by immunofluorescence. Mitochondrions were exposed to ultrasonic waves for up to 60 min by a piezoelectric transducer of frequency, 10 to 12 watt/cm² intensity and 10 to 12 MHz frequency.

The mitochondria were isolated by the method of H. R. Crane and J. D. Strehler (1961). The mitochondria were suspended in a 0.25 M sucrose solution. The suspension consisted of 1 mg of mitochondria per ml of sucrose. The activity was determined by measuring the rate of oxygen consumption as a substrate, measured by a Clark-type oxygen electrode. In addition, the suspensions were centrifuged at 100,000 g for 1 hour in a Beckman ultracentrifuge, and the supernatant was assayed for activity.

... suspensions were centrifuged at 105,000 g (1 hr) with a "Spinco" ultracentrifuge, and ultrathin mitochondrion sections were examined with a UEM-100 electron microscope. Findings are that the monoaminoxidase activity of mitochondrion suspensions exposed to ultrasonic waves does not differ from control suspensions. With centrifuging of control suspensions, monoaminoxidase activity was found in the supernatant. However, with ultracentrifuging of control suspensions, monoaminoxidase was found in the sediment. These results show that the liver submicroscopic structures, mitochondria, contain monoaminoxidase enzyme are only 10-15% of the total.
